Introduction

In today's digital age, accessing information quickly and efficiently has become essential. Wikipedia is one of the largest online encyclopedias, providing information on a wide range of topics. However, users often need a simple and convenient way to search for information and consume content according to their preferences. To address this need, the Wikipedia Search and Text-to-Speech Application has been developed.

The main objective of this project is to allow users to search for any topic directly from Wikipedia and instantly retrieve relevant and accurate information. The application uses the Wikipedia API to fetch article content and display search results in a user-friendly format. This eliminates the need to manually browse multiple web pages and helps users access knowledge quickly and efficiently.

A distinctive feature of the application is its integrated Text-to-Speech (TTS) functionality. This feature converts the retrieved text into spoken audio, enabling users to listen to Wikipedia articles instead of reading them. The audio feature enhances accessibility for visually impaired users, individuals with reading difficulties, and users who prefer auditory learning or multitasking while consuming information.

The project combines web technologies, information retrieval, and speech synthesis to create an informative and accessible platform. By offering both reading and listening options, it improves user engagement and accommodates diverse learning styles. The application demonstrates how modern technologies can be used to make information more accessible, interactive, and user-friendly.

Overall, the Wikipedia Search and Text-to-Speech Application is an effective solution for knowledge discovery, providing users with a seamless experience for searching, reading, and listening to information from Wikipedia in a single platfo
